In a Stroop task, participants are presented with a list of words, with each word displayed in a color of ink. The participant's task is to say out loud the color of the ink in which the word is printed. The task has two conditions: a congruent words condition, and an incongruent words condition. In the congruent words condition, the words being displayed are color words whose names match the colors in which they are printed: for example RED, BLUE. In the incongruent words condition, the words displayed are color words whose names do not match the colors in which they are printed: for example PURPLE, ORANGE. In each case, we measure the time it takes to name the ink colors in equally-sized lists. Each participant will go through and record a time from each condition.

Q1: Question response correctly identifies the independent and dependent variables in the experiment.

The variable that is manipulated in this experiment: The conditions (Congruent and Incongruent, the way words are displayed)

And that is why, it is an independent variable.

Using dependent variable, the experiment tries to measure the change and in this case, it is the time taken to name the ink colors.

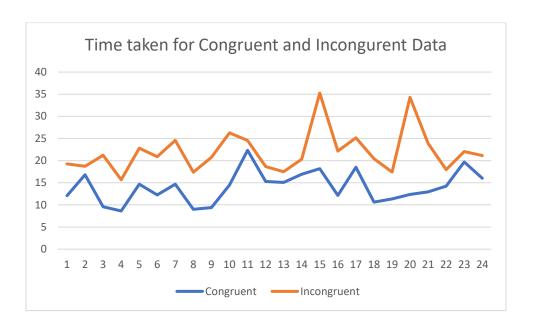

Q2a: Null and alternative hypotheses are clearly stated in words and mathematically. Symbols in the mathematical statement are defined.

Ho - **Null Hypothesis**: $(\mu - \mu i = 0)$ There is **not** significant difference in the average response time in reading out the congruent words(μ) vs viewing the incongruent(μ) words.

Ha - Alternative Hypothesis: (μ - μi <> 0)

The time taken to name the ink colors will vary for the two conditions.

Q2b: A statistical test is proposed which will distinguish the proposed hypotheses. Any assumptions made by the statistical test are addressed.

It is clear from the graph, that time taken for incongruent data is more than time taken for congruent data. We shall use T Test for dependent samples to verify this.

Since the same participants are present in both groups, we are going forward with this.

Moreover, we don't have data for the population, so we can't use Z Test.

Assumptions: There is sufficient difference between the time used to recognize colors under the two conditions so that one is not influenced by the other.

Q3: Descriptive statistics, including at least one measure of centrality and one measure of variability, have been computed for the dataset's groups.

	Congruent	Incongruent		
Mean	14.051125	22.01591667		
Median	14.3565	21.0175		
Standard Deviation	3.559357958	4.797057122		
Variance	12.66902907	23.01175704		

Mean and Median are measures of centrality. Std Dev and Variance are measures of variability.

They have been calculated in Excel.

Q4: One or two visualizations have been created that show off the data, including comments on what can be observed in the plot or plots.

getwd()

stroop <- read.csv("stroopdata.csv")</pre>

#Plotting the data

library(RColorBrewer)

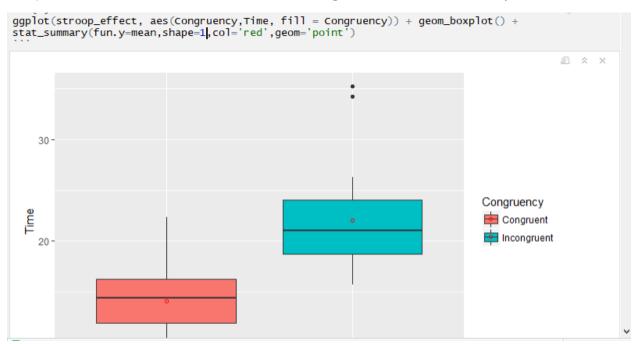

library(ggplot2)

 $ggplot(aes(x=Number, y=Time, color = Congruency), data = stroop_effect) + geom_point(alpha = 1) + geom_line()$

```

This plot makes it clear that time taken to read incongruent data is more for everyone.

To confirm the time again for the two types of methods, the mean and median are also visible in this plot.

Q5: A statistical test has been correctly performed and reported, including test statistic, p-value, and test result. The test results are interpreted in terms of the experimental task performed.

| Congruent | Incongruent | Difference |                          |                         |                   |                          | Chart Titl        | _           |

So, we can easily reject the null hypothesis and conclude that the difference between congruence and incongruence group time difference is statistically significant, namely, the Stroop effect is present.

Q6: Hypotheses regarding the reasons for the effect observed are presented. An extension or related experiment to the performed Stroop task is provided, that may produce similar effects.

Since we are familiar with those words and use them on daily basis, our cognitive powers are not that strong and hence we end up taking more time in the case of incongruent method.

An extension: We can add meaningless words to the list. (words that do not exist). In my opinion, it would take less time to read out the colors for those words.
